GreenCharge Mobility - Market Entry Analysis

Case Challenge 2026 - Problem Statement. GreenCharge Mobility is an electric-vehicle charging startup preparing to enter three Indian metro markets. The company operates forty-two fast-charging stations and has raised a Series A round of eighteen million dollars. The founding team must decide how to allocate capital across network expansion, dynamic pricing, and fleet partnerships over the next twenty-four months. Candidates are expected to analyze the competitive landscape, evaluate unit economics, and recommend a phased market entry strategy. Your submission should quantify the trade-offs between rapid geographic expansion and profitability, identify the two most material risks, and propose measurable milestones for the first four quarters. Cite all external sources and keep the analysis under twelve pages.

Our recommendation is a phased cluster strategy. GreenCharge should dominate two dense urban corridors before opening a third market. Charging networks exhibit strong local density economics: utilization rises superlinearly once a driver can rely on several stations within a five-kilometre radius, and utilization, not station count, determines station-level profitability.

The core competitive advantage relies on vertical integration of the energy procurement layer. By contracting solar capacity directly and operating its own battery buffering, GreenCharge can reduce effective energy cost per kilowatt-hour by roughly eighteen percent relative to grid purchasing. Operating margins expand accordingly, and the savings fund the software layer that drivers actually experience: reliable availability prediction, transparent queue times, and one-tap payment. Competitors that resell grid power at retail margins cannot match this cost structure without owning generation assets.

Dynamic pricing is the second lever. Demand follows a pronounced bimodal curve, with morning and evening peaks straining stations while midday capacity idles. A price spread of fifteen to twenty percent between peak and off-peak windows smooths utilization and lifts revenue per charger without meaningful customer attrition, because fleet drivers respond to predictable discounts.

The two material risks are grid interconnection delays, which can stall new sites by six months or more, and price undercutting by oil marketing companies entering the segment. We recommend quarterly milestones: station utilization above twenty-two percent by quarter two, energy cost per kilowatt-hour below six rupees by quarter three, and two signed fleet partnerships covering at least eight hundred vehicles by quarter four.
